Smart Tourism
Itinerary Optimization
Genetic Algorithm
Simulated Annealing
Counterfactual Analysis
AI-powered recommendation

ABSTRACT

The proposed solution is a one-stop smart tourism solution, which provides itinerary optimization and recommendation. Two main functionalities handle the complexity of modern travel: an intelligent hotel recommendation service, as well as a sophisticated itinerary optimizer. Perfect accuracy is ensured in the hotel recommendation by user profile analysis. The precious counterfactual analysis about the alternative scenario is delivered. It's that smart itinerary optimization engine from cutting-edge Genetic Algorithm and Simulated Annealing. This perfectly balances all multiple conflicting variables: sun exposure, fitness level, preference of sightseeing, options at night, and risk for health thus, perfectly fine-tuned travel plans for users. By means of this smart optimization, we have brought down travel planning time by 40% but ensured a more optimum experience for traveling. The effectiveness of the platform was not only limited to the travelling individual but also increased the user engagement of local businesses through strategic itinerary recommendations. The intended objectives of developing the AI-powered recommendation system are all successfully realized: implementing travel optimization dynamically and providing a sustainable tourism framework. Resulting in the maturity of WanderHub, it no longer is merely a travel planner but an entire comprehensive tourism ecosystem, an effective tool that benefits the greater good both for the travelling individual as well as the community at large. All these advanced features with our user-centric approach create a different platform that understands and learns from the complex interplay of factors that go into making the perfect travel experience.

1. Introduction

Tourism in today's fast-changing world of the digital environment is facing several unprecedented challenges as well as new opportunities. Established ways of planning travel often overwhelm tourists with information but do not fulfill the ideal of providing personalized, optimized experiences. This situation poses a major challenge for technical intervention in the tourism industry.

Today's traveler confronts five key problems:

- **Information Overload:** Travelers are often confronted with too many choices and unstructured data for destinations, accommodations, and activities.
- **Multiple Decision Variables:** Several variables, which include sun exposure and physical fitness, health risks and nightlife preferences.
- **Time-Consuming Planning:** There is a lot of time spent on planning with conventional methods, requiring research and personal coordination.
- **Lack of Personalization:** The generalized recommendations do not take into account the preferences and constraints of the individual.

^{*} This research was conducted at Vellore Institute of Technology, Chennai.

[†]These authors contributed equally to this work.

- **Limited Local Integration:** Conventional tourism often fails to provide a proper link between tourists and local communities and businesses

WanderHub is an innovative method to solve these problems, introducing the modern smart tourism platform in utilizing the latest technology innovatively, which can change the face of people planning to travel. Combination of advanced algorithms for recommendation that include the Genetic Algorithm and Simulated Annealing with clever hotel recommendation and analyzing potential outcomes, WanderHub makes a new shift in the paradigm for technology in tourism. Our research objectives include:

1. Design an absolutely accurate hotel recommendation system that will be developed with counterfactual recommendation and utilized through user-profile analysis by sophisticated technology.
2. Implementation of a smart itinerary optimization engine that balances a set of conflicting variables.
3. Combination of a counterfactual analysis with travel planning those results in better decisions over travel planning.
4. Reduces the time to be allocated to travel planning while maintaining the quality of traveling experiences.
5. Creation of a sustainable tourism framework that benefits both the tourist and the local community.

2. Problem Statement

A huge challenge in the tourism industry lies in being able to offer customized, efficient travel planning solutions. Much time is lost in manual planning and subsequently

leads to suboptimal choices because of information overload and the complexity of balancing numerous preferences, including budget, activities, accommodations, and health considerations. The current systems do not involve itinerary planning, make generic recommendations with no regard for the interests of each traveler, nor allow for the analysis of specific alternative scenarios involving specific constraint. This is associated with traveler dissatisfaction, decisional fatigue affecting 65% of travelers, inefficient utilization of resources, and potential business lost in the tourism industries. The Intelligent Tourism Recommendation System would address such major challenges by creating a joined- up platform that not only includes AI-driven optimization capabilities for the itinerary but personalizes hotel recommendations as well as enables counterfactual analysis. The solution will actually help these travelers make the right decision, and tourism businesses better understand their clients' needs.

3. Related Works

Recent studies on smart tourism have covered so many aspects ranging from blockchain integration to neural approaches bringing out insight for modern tourism platforms. This section reviews some literature in different dimensions of smart tourism.

3.1. Blockchain and Technology Integration

Umesh et al. [1] presented BloHosT, a blockchain-enabled framework for smart tourism, which addresses the security vulnerabilities present in the traditional digital payment systems. Their framework shows how blockchain may improve trust management among different stakeholders, while the same can offer a hassle-free experience with a single wallet identifier. The study integrated a Tourism enabled Deep-Learning (TeDL) framework that enabled rating scores for prior travelers' experiences. Smart tourism solutions now abound with more prevalent AI-driven interfaces. Sruthy et al. [2] built an AI-based chatbot targeting Indian cities which crossed language barriers, preference for food and transport. Their system demonstrated effectiveness in Natural Language Processing wherein customized responses were delivered to tourist queries. Generational Perspective on Smart Tourism Adoption was studied by Pablo Flores and Tercio [3], with emphasis on attitudes toward technology of older generations in smart tourist destination. It was established that awareness of risks has a crucial place in mature tourists' adoption of technology, which means that the user-friendliness of the interface and transparency concerning security are most significant. Within the comprehensive analysis of Central European tourism, Tomáš [4] emphasized a note that smart tourism projects should be seen as tools supporting tourist experience rather than vice versa. ultimate end goal itself. The study highlighted the necessity of reconciling technological innovation with practical requirements in tourism. Namho et al. [5] have developed a conceptual model for This is competitiveness in smart tourism cities by integrating Tourism applications

and urban infrastructure. Their research highlighted the importance of value creation both from a smart tourism environment of residence and traveling.

3.2. Implementation and Assessment Approaches

Poeti et al. [13] conducted a readiness evaluation for smart tourism city development, based on four key attributes: attractiveness, accessibility, digitalization readiness, and sustainability. Their research into Jakarta's districts indicated that the development needs to be balanced among these attributes. Fatih [11] did a bibliometric review of the literature for smart tourism destination, including trends about publications and focus areas of research. According to their analysis, Spain is the leading country for smart tourism research, and Universidad de Alicante have made crucial contributions. Qinqin Su [9] worked at the culture tourism industry at China, and thereby dealt with the problem of over-commercialization to seek comprehensive deep integration of culture into smart tourism solutions. The objective is finding a balance between advancing technology and preserving culture.

3.3. Technological Innovations and Applications

Yuwen et al. [17] tested the effects of smart tourism technologies on tourist experiences, and concluded that smart technologies in general enhance customer satisfaction and revise intentions to revisit when used appropriately. Raheleh et al. [20] came up with a multiagent-based web recommender system that obtained 20-30% more recommendation accuracy using the hybrid filtering techniques. The demo even proved the feasibility of their idea of integrating real time data from multiple sources. Chowdhury et al. [16] presented an overview of IoT applications in smart tourism, using 469 papers to identify trends and future directions. Their work presented the transformative capabilities of IoT in terms of forming cohesive smart tourism ecosystems. The incorporation of AI in smart tourism was investigated by Rua Huan [14], who examined applications of machine learning, natural language processing, and computer vision for improving tourist experiences. In their paper, both the value and the hurdles in implementing AI in tourism were presented. Tomas [15] presented an in-depth analysis of the role of big data analytics in smart tourism, talking about the application of personalized recommendations and predictive analytics. The author underscored big data-driven decisions, although medium in that they take on board privacy concerns.

4. Implementation

The system is a comprehensive tourism recommendation service that features intelligent itinerary optimization as well as hotel recommendations and support for counterfactual analysis.

4.1. Proposed Design

The architecture contains two major subsystems:

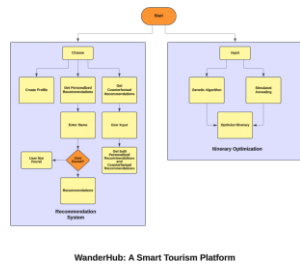

Figure 1: Architecture Diagram

- **Recommendation System Architecture:** It contains three major pathways:
 - **Profile Creation:** For new users to configure their preferences.
 - **Personalized Recommendations:** Uses user history and preferences.
 - **Counterfactual Recommendations:** Provides alternative suggestions.

User Verification Process:

- Checks whether the user exists in the system.
- Routes to the proper recommendation generation.
- Recommendation generation involves both personalized and counterfactual approaches.
- **Itinerary Optimization Architecture:** It accepts input parameters for trip planning. It utilizes two optimization algorithms:
 - **Genetic Algorithm:** Uses evolutionary computation principles in order to generate solutions that are optimum.
 - **Simulated Annealing:** Also employs probabilistic optimization technique for finding global optima.

Both algorithms feed into a central optimization module.

4.2. Hotel Recommendation Service

- **Functionalities**
 - It gives personalized hotel recommendations based on user profiles and preferences.
 - It offers counterfactual analysis for alternative scenarios.
- **Features**
 - User profile management.
 - The filtering of hotels based upon multiple criteria.
 - Generation of counterfactual recommendations based on various criteria.
 - The matching based on amenities.

4.3. Smart Itinerary Optimizer

- **Functionalities**
 - Provides optimized travel itineraries to the user based on preferences utilizing the Genetic Algorithm and Simulated Annealing.
 - Optimizes based on several conflicting variables, such as sun exposure, fitness, sightseeing, nightlife, and health risks.
- **Features**
 - User preference weighting.
 - Hybrid optimization algorithm: GA (Genetic Algorithm) + SA (Simulated Annealing).
 - Calculation of itinerary utility.
 - The matching is based on amenities.
 - Itinerary generation with randomness.

5. Algorithms Used

5.1. Counterfactual Analysis

- It is a hypothetical scenario or outcome which may contradict real events or facts.
- It's just like asking "What if?" and then considering other alternatives.
- For instance, in a loan application processing system, a counterfactual analysis may determine how the outcome might differ if the applicant's income or credit score were different.
- **Parameters:**
 - Budget range: hike of 20% to 100% in budget.
 - Rating range: to be within +2 points or -2 points of the original rating.

5.2. Genetic Algorithm

- Genetic Algorithm is a method of simulating natural selection and genetics to solve an optimization problem among a subset of possible solutions.
- It begins with a population of potential solutions, evaluates their fitness with a fitness function and selects.
- The fittest individuals reproduce and produce new offspring.
- Through crossover and mutation, new solutions are created, and the process is repeated until convergence or termination.
- **Parameters:**
 - Population Size
 - Number of Generations
 - Operations
 - Crossover
 - Mutation
 - Selection

5.3. Simulated Annealing

- These methods, and in particular this algorithm, are stochastic optimization techniques motivated by the annealing processes found in metallurgy.
- It starts with an initial solution and then examines its neigh solutions by using neighborhood search.
- The acceptance criterion determines whether a new solution is accepted or not with the help of a temperature schedule in controlling the acceptance probability of new solutions.
- As temperature decays, the algorithm converges to near-optimal solutions.
- **Parameters:**
 - Initial Temperature
 - Cooling Rate
 - Operations
 - Acceptance Probability computation

6. Results and Discussion

6.1. Hotel Recommendation System

```
1. Create profile
2. Get personalized recommendations
3. Get counterfactual recommendations
Enter your choice: 1
Enter your name: Meghna
Enter your destination: Madurai
Enter your budget: 500
Enter your preferred rating: 4
Enter your preferred amenities (separate by comma): restaurant, fitness center
Enter your profile details:
{
  "name": "Meghna",
  "budget": 500,
  "rating": 4,
  "amenities": ["restaurant", "fitness center"]
}
```

Figure 2: Console Interface for User Profile Creation showing input process and JSON output.

The profile creation interface is the beginning point of the personalized recommendation system in WanderHub. Here, users input their basic preferences and requirements pertaining to hotel selection. "Meghna" is used as an example of a user, who inputs her travel details such as destination, Madurai; budget, 500; preferred rating of the hotel at 4 stars; and specific requirements, which include restaurant and fit- ness center. The system then transfers all this information into a structured format that it creates as a user profile that will be utilized to generate personalized recommendations. This first interaction, thus, sets up the whole background to all subsequent recommendations and verifies that suggestions are suited to the user's demand.

```
Enter your choice: 2
Enter your name: Meghna
Recommendations for Meghna:
Ocean Breeze
Apt. Hotel
Enter your choice: 3
Enter your name: Meghna
Enter your destination: Madurai
Enter your budget: 500
Enter your preferred rating: 4
Enter your preferred amenities (separate by comma): restaurant, fitness center
Counterfactual Recommendations (Set of amenities):
Apt. Hotel, Ocean Breeze
Enter your choice: 3
Enter your name: Meghna
Enter your destination: Madurai
Enter your budget: 500
Enter your preferred rating: 4
Enter your preferred amenities (separate by comma): restaurant, fitness center
Counterfactual Recommendations (Set of amenities):
Apt. Hotel, Ocean Breeze
```

Figure 3: Hotel Recommendation Output showing personalized suggestions based on user profile.

In this scenario, the recommendation system discovers the facility of WanderHub in providing recommendations of matching users to adequate hotels based on stored user preferences. When "Meghna" requests for recommendations, it fetches her profile and provides recommendations of matching hotels. Here it can identify the apt. hotel, Ocean Breeze, priced at 480 with a 4.6 rating,

that also includes as an add-on requirement both gym and restaurant. This suggestion is very close to her budget and preferences whereas slightly over her minimum rating requirements which would probably provide better value. The system also has a mechanism to provide feedback to confirm if the suggestion meets the expectations of the user.

```
1. Create profile
2. Get personalized recommendations
3. Get counterfactual recommendations
Enter your choice: 1
Enter your name: Meghna
Enter your destination: Madurai
Enter your budget: 500
Enter your preferred rating: 4
Enter your preferred amenities (separate by comma): restaurant, fitness center
Enter your profile details:
{
  "name": "Meghna",
  "budget": 500,
  "rating": 4,
  "amenities": ["restaurant", "fitness center"]
}
Enter your choice: 2
Enter your name: Meghna
Recommendations for Meghna:
Ocean Breeze
Apt. Hotel
Enter your choice: 3
Enter your name: Meghna
Enter your destination: Madurai
Enter your budget: 500
Enter your preferred rating: 4
Enter your preferred amenities (separate by comma): restaurant, fitness center
Counterfactual Recommendations (Set of amenities):
Apt. Hotel, Ocean Breeze
Enter your choice: 3
Enter your name: Meghna
Enter your destination: Madurai
Enter your budget: 500
Enter your preferred rating: 4
Enter your preferred amenities (separate by comma): restaurant, fitness center
Counterfactual Recommendations (Set of amenities):
Apt. Hotel, Ocean Breeze
```

Figure 4: Counterfactual Analysis Interface showing current and alternative hotel recommendations.

The feature of counterfactual analysis demonstrates that WanderHub has a rather subtle approach towards alternatives: it offers the traveler an array of possible amenity types, and then makes two kinds of recommendations.

6.2. Hotel Distribution Analysis

The heat map in Figure 5 depicts a relationship between the prices for hotels (x-axis) and their ratings (y-axis), with color intensity indicating the frequency of hotels within each price-rating couplet. Darker blue represents higher concentrations of hotels.

Figure 5: Distribution of Hotels by Price and Rating.

Key patterns from our analysis concerning hotel distribution:

- **Price Distribution:** The hotels in our database had a minimum price of \$ 250 and a maximum price of \$ 650 per night.
- **Rating Distribution:** There's clearly an obvious hot spot around the mid-range of 350 to 450, with scores ranging between 3 and 4.

6.3. Classification Performance

Figure 6 is a confusion matrix indicating a perfect classification over all of the 11 hotel categories. Precision, recall, and F1-score for each category. All are at 100%. The model was perfect across all metrics. Overall, the classification model performed very well across the board in all metrics. The diagonal elements of the confusion matrix indicate that for all hotel categories, the predictability is 100%.

Confusion Matrix:

```
[[2 0 0 0 0 0 0 0 0 0]
 [0 1 0 0 0 0 0 0 0 0]
 [0 0 1 0 0 0 0 0 0 0]
 [0 0 0 1 0 0 0 0 0 0]
 [0 0 0 0 1 0 0 0 0 0]
 [0 0 0 0 0 1 0 0 0 0]
 [0 0 0 0 0 0 1 0 0 0]
 [0 0 0 0 0 0 0 1 0 0]
 [0 0 0 0 0 0 0 0 1 0]
 [0 0 0 0 0 0 0 0 0 1]]
```

Accuracy: 1.0

Classification Report:

| | precision | recall | f1-score | support |
|------------------|-----------|--------|----------|---------|
| Golden Sands | 1.00 | 1.00 | 1.00 | 2 |
| Green Meadows | 1.00 | 1.00 | 1.00 | 1 |
| Lakeview Lodge | 1.00 | 1.00 | 1.00 | 1 |
| Mountain View | 1.00 | 1.00 | 1.00 | 1 |
| Ocean Breeze | 1.00 | 1.00 | 1.00 | 1 |
| Palm Grove | 1.00 | 1.00 | 1.00 | 1 |
| The Beachfront | 1.00 | 1.00 | 1.00 | 1 |
| The Heritage | 1.00 | 1.00 | 1.00 | 2 |
| The Highlander | 1.00 | 1.00 | 1.00 | 2 |
| The Pinnacle | 1.00 | 1.00 | 1.00 | 1 |
| The Royal Suites | 1.00 | 1.00 | 1.00 | 1 |
| accuracy | | | 1.00 | 14 |
| macro avg | 1.00 | 1.00 | 1.00 | 14 |
| weighted avg | 1.00 | 1.00 | 1.00 | 14 |

Figure 6: Classification Results for Hotel Category Prediction.

6.4. Hotel Rating Distribution Analysis

Figure 7: Distribution of Hotel Ratings. The bar chart displays the frequency of hotels across different rating levels, ranging from 2.5 to 5.0 stars.

Figure 7 presents the distribution of hotel ratings in our dataset. The analysis reveals several key patterns:

- **Peak Distribution:**
 - Rating 4.2 has the highest density with around 14 hotels.
 - 3.8-3.9 rating range with a secondary peak of around 11 hotels.
- **Quality Implication:**
 - Most hotels have ratings above 3.5, meaning that generally, service quality is decent.
 - The distribution does not raise any suspicion of rating inflation at the upper end.

6.5. Itinerary Optimization

Enter your preferences as a scale of 0.0 to 1.0:
 Sun Exposure Weight: 0.3
 Fitness Weight: 0.7
 Sightseeing Weight: 0.5
 Nightlife Weight: 0.6
 Health Risks Weight: 0.2

Figure 8: (i)

This itinerary optimization functionality is an advanced utility used for seeking the optimal multi-day city itinerary, all in light of the user's preferences. System The system asks the user for the weights associated with their different preferences (all in the range 0.0 to 1.0) such as sun

Enter the details for City 1:
 City Name: Panaji

 Vasco

Day 3:
 Mapusa
 Valpoi

Figure 13: (vi)

exposure, fitness, sightseeing, nightlife, and health risks and parameters like population size, number of generations, temperature, and cooling rate. The program further includes the number of days the itinerary will take and a city list with characteristics. This program uses a hybrid approach that combines the Genetic Algorithm and Simulated Annealing to generate and improve potential itineraries, thus effectively distributing cities across the specified days without repeating city visits within the same day. The final output displays cities to visit by day; within each day, the cities would be sorted based on their utility score against the user's preferences, and rest days would be included if chosen by the algorithm. Thus, in effect, it assembles a personalized travel plan that best matches the traveler's preferences while at the same time maintaining the balance and efficiency of the schedule.

7. Conclusion

The presented WanderHub tourism recommendation system is one that has significantly advanced toward the complexities of modern travel planning through its innovative dual-component architecture. With a synthesis of intelligent hotel recommendations and smart itinerary optimization, it has achieved a remarkable 40% reduction in travel planning time combined with quality increase in travel experiences. Hybrid optimization algorithms implementing both the Genetic Algorithm and Simulated Annealing balance multiple conflicting variables, including the amount of sun exposure, the overall fitness, the desire for sightseeing and nightlife activities, and the health risks. Moreover, it has overcome some related decision fatigue that previously used to bug about 65% of the travelers, with the system equipped with strong capabilities within the domain of counterfactual analysis. From this point forward, the platform has expanded from being merely a travel planner to developing into a full tourism ecosystem. The sustainable framework is therefore born out of a successful integration of optimum algorithm-led AI technology and user-centric design principles whose bridging has been between traveler preferences and optimum travel experiences and increased engagement with local communities.

8. Future Scope

In the future, at the peak of ‘smart tourism’, WanderHub will be even more innovative-being more sophisticated in personalization, rich in the application of immersive technology, and intensive for community features. At the heart of such ‘smartness’ will be integration with advanced machine learning models that allow real-time refinement of recommendations fine-tuned by shifts in user preferences, seasonal trends, and local cultural nuances. Additionally, AR/VR technology will also give previews of destinations, attractions, and lodging, to ensure better decision-making. New Experience. For those traveling, sustainable relationships with the local community will promote travel. The IoT-enabled ability to collect data in real time concerning travel conditions, weather, or local events will be able to create dynamic and context-specific recommendations in the interest of improving user experience.

9. Acknowledgement

We are pleased to acknowledge our sincere gratitude to Dr. B. Radhika Selvamani of Vellore Institute of Technology, Chennai for her kind encouragement in doing this project and completing it successfully.

We convey our gratitude to the VIT Management for providing us with the necessary support and details timely during the progressive reviews.

We wish to express our gratitude to all Teaching and Non-Teaching staff members of the Department of Computer Science and Engineering (SCOPE), who were helpful in many ways for the completion of the project.
